

# Spec == Code: Pure functional Agent-Based Modelling

Jonathan THALER

February 6, 2017

## Abstract

Building upon our previous work on update-strategies in Agent-Based Simulation ABS where we showed that Haskell is a very attractive alternative to existing object-oriented approaches we ask in this paper if the declarative power of the pure functional language can be utilized to write specifications for simple models of ABS which can be directly translated to our Haskell implementation. We take two well known examples: the SIR and Prisoners Dilemma and express them in our model-specification language and show that they are in fact equals to haskell-code. Thus the novelty of this paper is a formalization of the specification of the latter one, which has been so far neglected.

## 1 Introduction

the specification language should not be too technical, its focus should be on non-technical expressiveness. The question is: can we abstract away the technicalities and still translate it directly to haskell (more or less)? If not, can we adjust our Haskell implementation to come closer to our specification language? Thus it is a two-fold approach: both languages need to come closer to each other if we want to close the gap

TODO: [2], [1] it is still not exactly clear  $=_j$  we present a formal specification using ABS

## 2 Related Research

[4] present an EDSL for Haskell allowing to specify Agents using the BDI model. We don't go there, thats not our intention.

TODO: [3]

TODO: [5]

TODO: cite julie greensmith paper on haskell

We don't focus on BDI or similar but want to rely much more on low-level basic messaging. We can also draw strong relations to Hoare's Communicating Sequential Processes (CSP), Milner's Calculus of Communicating Systems

(CCS) and Pi-Calculus. By mapping the EDSL to CSP/CCS/Pi-Calculus we achieve to be able to algebraic reasoning in our EDSL. TODO: hasn't Agha done something similar in connecting Actors to the Pi-Calculus?

### 3 Background

for exact specification, we also need the update-strategy. we show that there is very small differences in code but, as reported in [?] make huge differences in the results. note that the difference between SEQ and PAR in Haskell is in the end a 'fold' over the agents in the case of SEQ and a 'map' in the case of PAR

### 4 The specification Language

An Agent A is a 5-tuple  $\langle \text{Aid}, s, m, e, [\text{tf}] \rangle$ . Aid is the id of the agent s is the generic state of the agent m is the message-protocoll the agent understands including the messages (Dt d) and (Terminate) e is the generic environment the agent acts upon tf is a transformer-function for every message in the protocol (if an agent wants to ignore the message, it is just the identify function id) the type of a tf depends on the semantics of the model and there are 4 of them  
 SEQ:  $\text{tf} :: (A, e) \rightarrow (Aid, m) \rightarrow (A, e)$  PAR:  $\text{tf} :: (A, \text{Global } e) \rightarrow (Aid, m) \rightarrow (A, \text{Local } e)$  CON:  $\text{tf} :: (A, e) \rightarrow (Aid, m) \rightarrow STM\ A$  STM A  
 Local e = e Global e = Map Aid (Local e)  
 further the agent has the following functions at its hands  $\text{sendMessage} :: A \rightarrow Aid \rightarrow m \rightarrow A$

### 5 SIRS Specification

### 6 Prisoners Dilemma Specification

### 7 Results

### 8 Conclusion

### 9 Further Research
